Acute and chronic toxicity in liver and kidney of perch *Perca fluviatilis*, associated to carbamazepine exposure. Carbamazepine (CBZ) is a widely used antiepileptic drug, present in the environment through sewage treatment works effluents, which is potentially harmful to wildlife. Our study included a persistent exposure experiment, carried out with adult females of perch *Perca fluviatilis*, in a flow-through system with continuous flow of CBZ spiked water for 10 months. Samples of perch liver and kidney were collected every 2 weeks and analyzed to assess acute and chronic effects of CBZ on perch tissues. Microbiological, hematological and clinical chemistry analyses were performed on blood samples. The lethality rate was considerably higher in perch exposed to CBZ and amoxicillin compared to controls after 20 days exposure. At the end of the experiment, CBZ-exposed fish had higher mortality rates and abnormal clinical parameters (higher mortality, higher haemorrhagic values and blood protein concentration) and alterations in kidney (lower water content and in osmolarity). Organ and tissue weights were significantly increased in treated fish compared to controls. Histopathological alterations, mainly from hepatic and renal parenchyma were found. In addition, metabolizing enzymes (glutathione S-transferase and cytochrome P450) activities were measured in fish liver and kidney. Moderate induction of cytochrome P450 was shown by CBZ-treated fish. This study shows the potential for CBZ to induce both acute and chronic sublethal toxicity in perch.
